# CHARACTERIZATIONS OF $FV$ -RINGS BY QUASI-CONTINUOUS MODULES

J. AHSAN AND L. ZHONGKUI

## 1. INTRODUCTION

A ring  $R$  is called a left  $V$ -ring if every simple left  $R$ -module is injective. It is proved in Hiremath [9] that  $V$ -rings are precisely those in which every finitely cogenerated left  $R$ -module is injective. This result is generalized by Garcia Hernandez and Gomez Pardo in [6] in which  $V$ -rings relative to left Gabriel topologies on  $R$  are studied. It is proved in [6] that a ring  $R$  is an  $FV$ -ring if and only if every  $F$ -torsionfree and  $F$ -finitely cogenerated left  $R$ -module is dense in its injective envelope. In this paper, we give the characterizations of  $FV$ -rings by proving that, if  $F$  is a left Gabriel topology on  $R$  such that all quasi-continuous left  $R$ -modules are  $F$ -injective, then  $R$  is an  $FV$ -ring if and only if every  $F$ -torsionfree and  $F$ -finitely cogenerated left  $R$ -module is dense in its some essential extensions which are quasi-continuous. As a corollary we deduce that a ring  $R$  is a  $V$ -ring if and only if every finitely cogenerated left  $R$ -module is continuous (if and only if every finitely cogenerated left  $R$ -module is quasi-continuous). Also we consider a particular case when  $F$  is a strongly semiprime left Gabriel topology on  $R$ , and obtain new characterizations of  $FV$ -rings which, for trivial  $F$ , give characterizations of left  $V$ -rings. For example, we show that  $R$  is a left  $V$ -ring if and only if every finitely quasi-copresented left  $R$ -module is quasi-injective, where a left  $R$ -module  $M$  is called finitely quasi-copresented if  $M$  and  $E_q(M)/M$  are finitely cogenerated where  $E_q(M)$  is the quasi-injective envelope of  $M$ .

## 2. PRELIMINARIES

All rings considered in this paper are associative with identity and unless otherwise mentioned all modules are unitary left  $R$ -modules. For any module  ${}_R M$  we denote by  $E(M)$ ,  $E_q(M)$ ,  $E_{vN}(M)$  and  $Soc(M)$  the injective envelope, the quasi-injective envelope (see [5]), the  $vN$ -injective envelope (see [13]) and the socle of  $M$ , respectively.

Let  $M$  be a left  $R$ -module. Recall that  $M$  is called a *CS-module* provided every submodule of  $M$  is essential in a direct summand of  $M$ , or equivalently, every maximal essential extension of a submodule  $M$  is a direct summand of  $M$  (see [2] or [3]).  $M$  is called continuous if  $M$  is a *CS-module* and every submodule isomorphic to a direct summand is a direct summand (see [10] or [11]).  $M$  is called *quasi-continuous* (or  $\pi$ -injective in [8]) if it is a *CS-module* and for any direct summands  $A$  and  $B$  of  $M$  with  $A \cap B = 0$ ,  $A \oplus B$  is also a direct summand of  $M$  (see [11] or [15]).

The following lemma and its simple proof appeared in [15].

**Lemma 2.1.** *Let  $M$  be a quasi-continuous  $R$ -module,  $M = B \oplus A$ . Then  $B$  is  $A$ -injective; that is, any homomorphism from a submodule of  $A$  to  $B$  extends to a homomorphism from  $A$  to  $B$ .*

Following [11] in which  $vN$ -injective modules were investigated, a module  $M$  is called  *$vN$ -injective* if  $f(M) \leq M$  for any von Neumann regular element  $f \in \text{End}_R(E(M))$ .

**Lemma 2.2.** (cf. [11] and [14]) *For any  $R$ -module, we have the following implications:*

*injective  $\Rightarrow$  quasi-injective  $\Rightarrow vN$ -injective  $\Rightarrow$  continuous  $\Rightarrow$  quasi-continuous.*

*Also all implications are one-sided.*

Let  $R$  be a ring and  $F$  a left Gabriel topology on  $R$ . According to Garcia Hernandez and Gomez Pardo [6], we say that  $R$  is an  $FV$ -ring if every simple object of the category  $(R, F)\text{-Mod}$  is injective. Note that if  $F = \{R\}$ , then  $FV$ -rings are precisely the left  $V$ -rings. On the other hand, if  $F$  is a perfect Gabriel topology, then the inclusion functor  $j : (R, F)\text{-Mod} \rightarrow R_F\text{-Mod}$  is an equivalence; hence,  $R$  is an  $FV$ -ring if and only if  $R_F$  is a left  $V$ -ring. If  $F$  is the left Goldie topology then the category  $(R, F)\text{-Mod}$  is a spectral category, so clearly  $R$  is an  $FV$ -ring.

An  $R$ -module  $M$  is called  $F$ -finitely cogenerated if  $M_F$  is a finitely cogenerated object of  $(R, F)\text{-Mod}$  (see [6]). We record below some well-known results often referred to in the proof of our theorems.

**Lemma 2.3.** ([6]) *Let  $M$  be an  $F$ -torsionfree  $R$ -module. If  $M$  is  $F$ -finitely cogenerated, then every family of  $F$ -torsionfree modules which cogenerates  $M$ , does cogenerate it finitely.*

**Lemma 2.4.** ([6]) *Let  $M$  be an  $F$ -torsionfree  $R$ -module. Then  $M$  is  $F$ -finitely cogenerated if and only if there exist  $F$ -cocritical modules  $C_1, \dots, C_n$  such that  $E(M) \cong \bigoplus_{i=1}^n E(C_i)$ .*

By analogy with the concept of  $\sigma$ -cyclic modules defined by Ahsan in [1], we have:

**Definition 2.1.** *Let  $F$  be a left Gabriel topology on  $R$  and  $M \in R\text{-Mod}$ .  $M$  is called an  $F$ -cocyclic  $R$ -module if there exists an  $F$ -cocritical module  $C$  such that the following sequence is exact:*

$$0 \rightarrow M_F \rightarrow E(C_F).$$

*$M$  is called a  $\sigma$ - $F$ -cocyclic  $R$ -module if  $M$  is a direct sum of finitely many  $F$ -cocyclic modules.*

Every  $F$ -cocritical module clearly is  $F$ -cocyclic, and so is  $\sigma$ - $F$ -cocyclic. If  $F = \{R\}$ , then  $F$ -cocyclic modules and  $\sigma$ - $F$ -cocyclic modules just are cocyclic modules defined in [9] and [12] and  $\sigma$ -cocyclic modules defined in [12], respectively.

**Lemma 2.5.** *Let  $M$  be an  $R$ -module, if  $M$  is  $\sigma$ - $F$ -cocyclic, then  $M$  is  $F$ -finitely cogenerated.*

**Proof.** It is easy to see that  $M = N_1 \oplus \cdots \oplus N_n$ , where every  $N_i$  is  $F$ -cocyclic. Hence there exist  $F$ -cocritical modules  $C_1, \dots, C_n$  such that the following sequence is exact:

$$0 \rightarrow M_F \rightarrow \bigoplus_{i=1}^n E(C_{iF}).$$

The result follows now since every  $C_{iF}$  is a simple object of category  $(R, F)\text{-Mod}$ . ■

### 3. MAIN RESULTS

**Theorem 3.1.** *Let  $F$  be a left Gabriel topology on  $R$ . If every quasi-continuous  $R$ -module is  $F$ -injective, then the following conditions are equivalent.*

- (i)  $R$  is an  $FV$ -ring.
- (ii) Every  $F$ -torsionfree and  $F$ -finitely cogenerated  $R$ -module is dense in its some essential extensions which are quasi-continuous.
- (iii) Every  $F$ -torsionfree and  $\sigma$ - $F$ -cocyclic  $R$ -module is dense in its some essential extensions which are quasi-continuous.
- (iv) For every  $F$ -torsionfree and  $F$ -finitely cogenerated  $R$ -module  $M$ , there exists a quasi-continuous  $R$ -module  $N$  with essential submodule  $M$  such that  $\text{Rad}_F(N) = 0$ .
- (v) For every  $F$ -torsionfree and  $\sigma$ - $F$ -cocyclic  $R$ -module  $M$ , there exists a quasi-continuous  $R$ -module  $N$  with essential submodule  $M$  such that  $\text{Rad}_F(N) = 0$ .

**Proof.** (i)  $\Rightarrow$  (ii). This follows from Theorem 2.2 of [6], which shows that if  $R$  is an  $FV$ -ring, then every  $F$ -torsionfree and  $F$ -finitely cogenerated  $R$ -module is dense in its injective envelope.

(ii)  $\Rightarrow$  (iii). This follows from Lemma 2.5.

(iii)  $\Rightarrow$  (i). The inclusion functor  $i : (R, F)\text{-Mod} \rightarrow R\text{-Mod}$  has a left adjoint  $a : R\text{-Mod} \rightarrow (R, F)\text{-Mod}$  which is exact and assigns to each  $M \in R\text{-Mod}$  its module of quotients  $M_F$ . Let  $C$  be a simple object of the category  $(R, F)\text{-Mod}$ . Then  $i(C) \in R\text{-Mod}$ . It is clear that  $i(C)$  and  $E(i(C))$  are  $F$ -cocyclic since  $i(C)$  is an  $F$ -cocritical module. Hence  $D = i(C) \oplus E(i(C))$  is a  $\sigma$ - $F$ -cocyclic module. The fact that  $D$  is  $F$ -torsionfree is also clear. By hypothesis, there exists an essential extension  $N$  of  $D$ , such that  $N$  is quasi-continuous and  $D$  is dense in  $N$ . Then it follows that

$$C \oplus E(C) \cong i(C)_F \oplus E(i(C))_F \cong D_F = N_F.$$

By assumption,  $N$  is an  $F$ -injective module. It is also clear that  $N$  is  $F$ -torsionfree. Therefore  $N$  is  $F$ -closed. So we have that  $D \cong i(N_F) \cong N$  is a quasi-continuous  $R$ -module. By Lemma 2.1,  $i(C)$  is  $E(i(C))$ -injective; that is, any homomorphism from a submodule of  $E(i(C))$  to  $i(C)$  extends to a homomorphism from  $E(i(C))$  to  $i(C)$ . Thus it is easy to see that  $i(C) = E(i(C))$ , which means that  $i(C)$  is an injective  $R$ -module. By Proposition X.1.4 of [16],  $C$  is an injective object of  $(R, F)\text{-Mod}$ . Therefore  $R$  is an  $FV$ -ring.

(ii)  $\Rightarrow$  (iv). Let  $M \in R\text{-Mod}$  be  $F$ -torsionfree and  $F$ -finitely cogenerated. By condition (ii), there exists an essential extension  $N$  of  $M$  such that  $N$  is quasi-continuous and  $M$  is dense in  $N$ . By Proposition 1.2 of [6] we have

$$(\text{Rad}_F(N))_F = \text{Rad}(N_F) = \text{Rad}(M_F).$$

Since  $M$  is  $F$ -finitely cogenerated, there exists  $F$ -cocritical  $R$ -modules  $S_1, \dots, S_n$  such the following sequence is exact:

$$0 \rightarrow M_F \rightarrow \bigoplus_{i=1}^n E(S_{iF}).$$

By the results proved above, when condition (ii) holds,  $R$  is an  $FV$ -ring. Therefore every simple object of  $(R, F)\text{-Mod}$  is injective. It follows that  $E(S_{iF}) = S_{iF}$ ,  $i = 1, \dots, n$ , which implies that

$$\text{Rad}(\bigoplus_{i=1}^n E(S_{iF})) = \bigoplus_{i=1}^n \text{Rad}(E(S_{iF})) = 0.$$

Therefore  $\text{Rad}(M_F) = 0$ . Thus  $\text{Rad}_F(N) = t(\text{Rad}_F(N))$ , where  $t$  is a left exact radical corresponding to the Gabriel topology  $F$ . This means that  $\text{Rad}_F(N)$  is an  $F$ -torsion module. On the other hand,  $\text{Rad}_F(N)$  is an  $F$ -saturated submodule of  $N$ , so is  $F$ -torsionfree. Thus we have  $\text{Rad}_F(N) = 0$ , as required.

(iv)  $\Rightarrow$  (v). This follows from Lemma 2.5.

(v)  $\Rightarrow$  (iii). Let  $M$  be an  $F$ -torsionfree and  $\sigma$ - $F$ -cocyclic  $R$ -module. Then there exists an essential extension  $N$  of  $M$  such that  $N$  is quasi-continuous and  $\text{Rad}_F(N) = 0$ . It follows from Proposition 1.3 of [6] that  $N$  is cogenerated by a class of  $F$ -cocritical modules.

Since  $M$  is  $\sigma$ - $F$ -cocyclic, by Lemma 2.5,  $M$  is  $F$ -finitely cogenerated. Thus there exist  $F$ -cocritical  $R$ -modules  $S_1, \dots, S_n$  such that  $E(M) \cong \bigoplus_{i=1}^n E(S_i)$ . Therefore  $N$  can be embedded in  $\bigoplus_{i=1}^n E(S_i)$  since  $N$  is an essential extension of  $M$ . This means that  $N$  is  $F$ -finitely cogenerated. By Lemma 2.3, there exist a finite number of  $F$ -cocritical  $R$ -modules  $C_1, \dots, C_n$  such that the sequence  $0 \rightarrow N \rightarrow \bigoplus_{i=1}^n C_i$  is exact, which implies that the following sequence is exact:

$$0 \rightarrow N_F \rightarrow \bigoplus_{i=1}^n C_{iF}$$

Therefore  $N_F$  is a semisimple object of  $(R, F)$ -Mod. On the other hand,  $M$  is an essential submodule of  $N$ , so  $M_F$  is essential in  $N_F$  by Lemma 0.1 of [6]. It is then easy to see that  $M_F = N_F$ , in other words  $M$  is dense in  $N$ , and we are done. ■

The following Corollary is a generalization of [13].

**Corollary 3.2.** *Let  $F$  be a left Gabriel topology on  $R$ . If every continuous  $R$ -module is  $F$ -injective, then the following conditions are equivalent.*

- (i)  *$R$  is an  $FV$ -ring.*
- (ii) *Every  $F$ -torsionfree and  $F$ -finitely cogenerated  $R$ -module is dense in its  $vN$ -injective envelope.*
- (iii) *Every  $F$ -torsionfree and  $F$ -finitely cogenerated  $R$ -module is dense in its quasi-injective envelope.*
- (iv) *Every  $F$ -torsionfree and  $F$ -finitely cogenerated  $R$ -module is dense in its injective envelope.*
- (v) *For every  $F$ -torsionfree and  $F$ -finitely cogenerated  $R$ -module  $M$ ,*  

$$\text{Rad}_F(E_{vN}(M)) = 0.$$
- (vi) *For every  $F$ -torsionfree and  $F$ -finitely cogenerated  $R$ -module  $M$ ,*  

$$\text{Rad}_F(E_q(M)) = 0.$$
- (vii) *For every  $F$ -torsionfree and  $F$ -finitely cogenerated  $R$ -module  $M$ ,*  

$$\text{Rad}_F(E(M)) = 0.$$

**Proof.** This follows from Lemma 2.2, from Theorem 2.2 of [6], and from the similar proof of Theorem 3.1. ■

**Corollary 3.3.** *The following conditions are equivalent.*

- (i)  *$R$  is a left  $V$ -ring.*

(ii) Every finitely cogenerated  $R$ -module is quasi-continuous (continuous,  $vN$ -injective, quasi-injective, injective, respectively).

(iii) Every  $\sigma$ -cocyclic  $R$ -module is quasi-continuous (continuous,  $vN$ -injective, quasi-injective, injective, respectively).

#### 4. A PARTICULAR CASE

Let  $M \in R\text{-Mod}$ . Recall that  $M$  is *finitely copresented* if and only if  $M$  and  $E(M)/M$  are finitely cogenerated (see [4]). By [6],  $M$  is called  *$F$ -finitely copresented* if  $M_F$  is a finitely copresented object of  $(R, F)\text{-Mod}$ . It is proved in [6] that if  $M$  is  $F$ -torsionfree, then  $M$  is  $F$ -finitely copresented if and only if  $M$  and  $E(M)/M$  are  $F$ -finitely cogenerated. We give the following definition.

**Definition 4.1.** Let  $F$  be a left Gabriel Topology on  $R$  and  $M \in R\text{-Mod}$ . We say  $M$  is  *$F$ -finitely quasi-copresented* ( *$F$ -finitely  $vN$ -copresented*, respectively) if  $M$  and  $E_q(M)/M$  ( $E_{vN}(M)/M$ , respectively) are  $F$ -finitely cogenerated. When  $F = \{R\}$ ,  *$F$ -finitely quasi-copresented  $R$ -modules* and  *$F$ -finitely  $vN$ -copresented  $R$ -modules* are called *finitely quasi-copresented* and *finitely  $vN$ -copresented*, respectively.

**Lemma 4.1.** For any  $R$ -module, we have the following implications.

$F$ -finitely copresented  $\Rightarrow$   $F$ -finitely quasi-copresented  $\Rightarrow$   $F$ -finitely  $vN$ -copresented  
 $\Rightarrow$   $F$ -finitely cogenerated.

*Proof.* . It follows from Definition 4.1 and Lemma 2.2. ■

The following example shows that there exists an  $F$ -finitely quasi-copresented  $R$ -module which is not  $F$ -finitely copresented.

**Example 4.1.** In a personal communication to V. Camillo and M. F. Yuosif, Patrick Smith pointed out that there are modules  $E$  with  $\text{Soc}(E)$  simple and essential and

$E/\text{Soc}(E)$  not finite dimensional (see [2]). Set  $M = \text{Soc}(E)$ . Then it is clear that  $M$  is finitely quasi-copresented. On the other hand, there exists a homomorphism  $f : E \rightarrow E(M)$  such that  $f|_M = i$ , where  $i : M \rightarrow E(M)$  is the inclusion mapping. Since  $M = \text{Soc}(E)$  is essential in  $E$ , it follows that  $f$  is monomorphism. Thus  $E/M$  is isomorphic to a submodule of  $E(M)/M$ . Hence  $E(M)/M$  is not finite dimensional, which implies that  $E(M)/M$  is not finitely cogenerated, and thus  $M$  is not finitely copresented.

**Lemma 4.2.** ([6]) *Let  $F$  be a strongly semiprime left Gabriel topology on  $R$ . If  $M \in R\text{-Mod}$  is not an  $F$ -torsion module, then  $M$  has a nonzero  $F$ -torsionfree and  $F$ -finitely cogenerated quotient.*

**Theorem 4.3.** *Let  $F$  be a strongly semiprime left Gabriel topology on  $R$ . Suppose that every quasi-continuous  $R$ -module is  $F$ -injective. Then the following conditions are equivalent.*

- (i)  $R$  is an FV-ring.
- (ii) Every  $F$ -torsionfree and  $F$ -finitely  $vN$ -copresented  $R$ -module is dense in its  $vN$ -injective envelope.
- (iii) Every  $F$ -torsionfree and  $F$ -finitely quasi-copresented  $R$ -module is dense in its quasi-injective envelope.
- (iv) For every left ideal  $I$  of  $R$ , if  $R/I$  is  $F$ -torsionfree and  $F$ -finitely cogenerated, then there exists a quasi-continuous  $R$ -module  $N$  with essential submodule  $R/I$  such that  $\text{Rad}_F(N) = 0$ .

Proof. . (i)  $\Rightarrow$  (ii) and (i)  $\Rightarrow$  (iii) follow from Lemma 4.1 above and Theorem 2.2 of [6].

(ii)  $\Rightarrow$  (i). From Theorem 3.1 we see that it is enough to prove that for every  $F$ -torsionfree and  $\sigma$ - $F$ -cocyclic  $R$ -module  $M$ , there exists a quasi-continuous  $R$ -module  $N$  with essential submodule  $M$  such that  $M$  is dense in  $N$ . Let  $M$  be an  $F$ -torsionfree and  $\sigma$ - $F$ -finitely cogenerated  $R$ -module. It is easy to see that there exists a quasi-continuous  $R$ -module  $N$  with essential submodule  $M$  ( $N = E(M)$ , or  $E_q(M)$  or  $E_{\nu N}(M)$ , for example).

Suppose that  $N = E_{\nu N}(M)$  and  $M$  is not a dense submodule of  $N$ . Then  $(N/M)_F \neq 0$  and so  $N/M$  is not an  $F$ -torsionfree module. By Lemma 4.2,  $N/M$  has a nonzero  $F$ -finitely cogenerated and  $F$ -torsionfree quotient,  $L$ , which is of the form  $N/K \cong (N/M)/(K/M)$  for some  $K$  such that  $M \leq K \leq N$ .

From Lemma 2.5 it is clear that  $M$  is  $F$ -finitely cogenerated, and so, by Lemma 2.4 there exist  $F$ -cocritical  $R$ -modules  $S_1, \dots, S_n$  such that  $E(M) \cong \bigoplus_{i=1}^n E(S_i)$ . Because  $K \leq N$  can be embedded to  $E(M)$ , we have the following exact sequence:

$$0 \rightarrow K_F \rightarrow \bigoplus_{i=1}^n E(S_{iF}),$$

which implies that  $K$  is  $F$ -finitely cogenerated. Now it is clear that  $K$  is  $F$ -finitely  $\nu N$ -copresented since  $N/K \cong L$  is  $F$ -finitely cogenerated. Therefore, by condition (ii),  $K$  is dense in its  $\nu N$ -injective envelope. It is easy to see that  $E_{\nu N}(M) = E_{\nu N}(K)$ , so  $K_F = (E_{\nu N}(M))_F$ . Hence  $E_{\nu N}(M)/K$  is an  $F$ -torsion module. On the other hand,  $E_{\nu N}(M)/K \cong L$  is  $F$ -torsionfree. Therefore  $L = 0$ , which is a contradiction. Hence  $M$  is dense in  $E_{\nu N}(M)$ , as required.

(iii)  $\Rightarrow$  (i). It is similar to (ii)  $\Rightarrow$  (i).

(i)  $\Rightarrow$  (iv). It follows from Theorem 3.1

(iv)  $\Rightarrow$  (i). Since  $F$  is strongly semiprime, the class of  $F$ -torsionfree modules is cogenerated by the direct sum of the injective envelopes of  $F$ -cocritical modules. Thus it suffices to prove that if  $C$  is  $F$ -cocritical, then  $E(C)$  is  $F$ -semisimple; that

is,  $E(C)_F$  is a semisimple object of  $(R, F)$ -Mod.

Let  $M$  be a cyclic submodule of  $E(C)$ . Then, since  $E(C)$  is  $F$ -finitely cogenerated,  $M$  is  $F$ -finitely cogenerated also. Clearly,  $M \cong R/I$ , where  $I$  is a left ideal of  $R$ . From condition (iv), there exists a quasi-continuous module  $N$  with essential submodule  $M$  such that  $\text{Rad}_F(N) = 0$ . Therefore, by Proposition 1.3 of [6],  $N$  is cogenerated by  $F$ -cocritical modules. It is clear that  $N$  is  $F$ -finitely cogenerated since  $N$  can be embedded in  $E(M)$ . Therefore  $N$  is a submodule of a finite direct sum of  $F$ -cocritical modules by Lemma 2.3, which implies that  $N$  is  $F$ -semisimple. It then follows that  $M$  is  $F$ -semisimple. It is clear that  $E(C)$  is a quotient of the direct sum of its cyclic submodules. Since the class of  $F$ -semisimple modules is closed under quotient modules and direct sums (see [7]), it follows that  $E(C)$  is  $F$ -semisimple. ■

**Corollary 4.4.** *Let  $F$  be a strongly semiprime left Gabriel topology on  $R$ . Suppose that every quasi-continuous  $R$ -module is  $F$ -injective. Then the following conditions are equivalent.*

(i)  $R$  is an  $FV$ -ring.

(ii)  $\text{Rad}_F(E_q(R/I)) = 0$  ( $\text{Rad}_F(E_{vN}(R/I)) = 0$ , respectively) for every left ideal  $I$  of  $R$  such that  $R/I$  is  $F$ -torsionfree and  $F$ -finitely cogenerated.

(iii) For every left ideal  $I$  of  $R$ , if  $R/I$  is  $F$ -torsionfree and  $F$ -finitely cogenerated, then there exists a continuous  $R$ -module  $N$  with essential submodule  $R/I$  such that  $\text{Rad}_F(N) = 0$ .

**Proof.** It follows from Theorem 4.3, Corollary 3.1, and Lemma 2.2. ■

In [6], it is proved that  $R$  is a left  $V$ -ring if and only if every finitely copresented  $R$ -module is injective. Here we have:

**Corollary 4.5.** *The following conditions are equivalent.*

- (i)  $R$  is a left  $V$ -ring.
- (ii) Every finitely quasi-copresented  $R$ -module is quasi-injective.
- (iii) Every finitely  $vN$ -copresented  $R$ -module is  $vN$ -injective.

Recall that a ring  $R$  is called left *conoetherian* if every quotient of finitely cogenerated  $R$ -module is finitely cogenerated. It is proved in [12] that  $R$  is a left  $V$ -ring if and only if every finitely copresented  $R$ -module is quasi-injective and  $R$  is a conoetherian ring. Here we have:

**Corollary 4.6.**  *$R$  is a left  $V$ -ring if and only if every finitely copresented  $R$ -module is quasi-continuous and  $R$  is left conoetherian.*

Proof.  $\Rightarrow$ ). It follows from [9].

$\Leftarrow$ ). Suppose that  $R$  is left conoetherian. Then it follows that every finitely cogenerated  $R$ -module is finitely copresented by [9]. Hence every finitely cogenerated module is quasi-continuous. Thus  $R$  is a left  $V$ -ring by Corollary 3.3. ■
